The map shows the distribution of forests in the Amazon region. The darker areas represent higher percentages of forest cover. The data is based on the RAISG (Red de Información Ambiental de Sudamérica) database and covers the year 2013.

The Amazon region is one of the most important biomes on Earth, covering more than 6 million square kilometers. It is home to an immense biological diversity and plays a crucial role in global climate regulation.

Forests in the Amazon region are facing significant threats, including deforestation due to agricultural expansion, logging, and infrastructure development. The rate of deforestation has decreased in recent years, but it remains a major concern for conservation.

The image also includes a table and a graph showing the extent of deforestation in different countries and over time. The data is sourced from the RAISG database and provides insights into the progress made in forest conservation efforts.

Overall, the image highlights the importance of the Amazon region and the need for continued efforts to protect and restore its natural resources.
